

docker

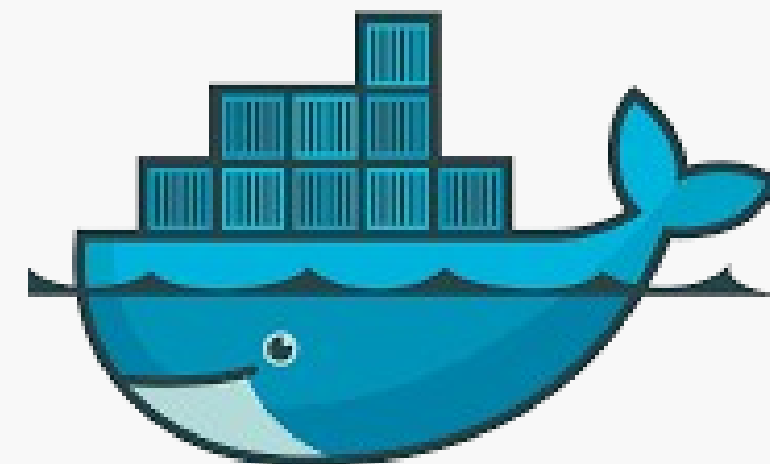

- **Containerization platform**
- **Allows you to package applications with all dependencies into isolated environments called containers.**

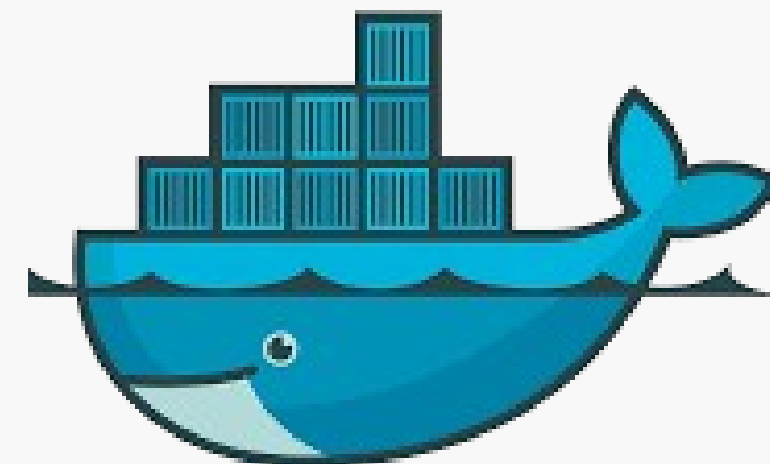

# Problem Without Docker?

**“It works on my machine  
but not on yours”**

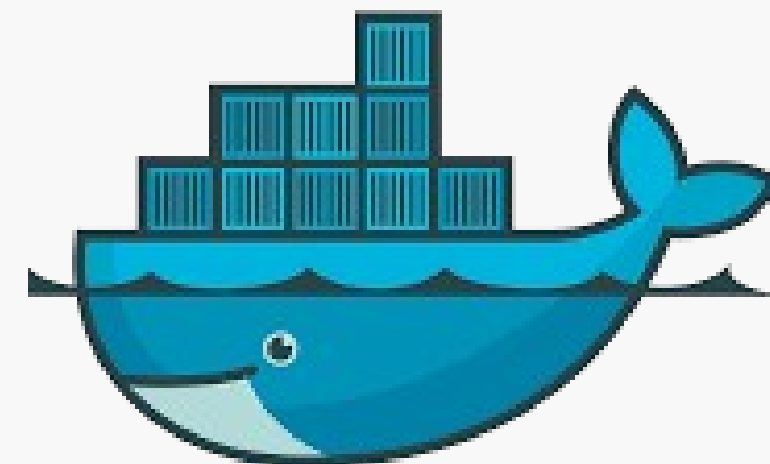

**“Applications break when  
moved from development  
to production”**

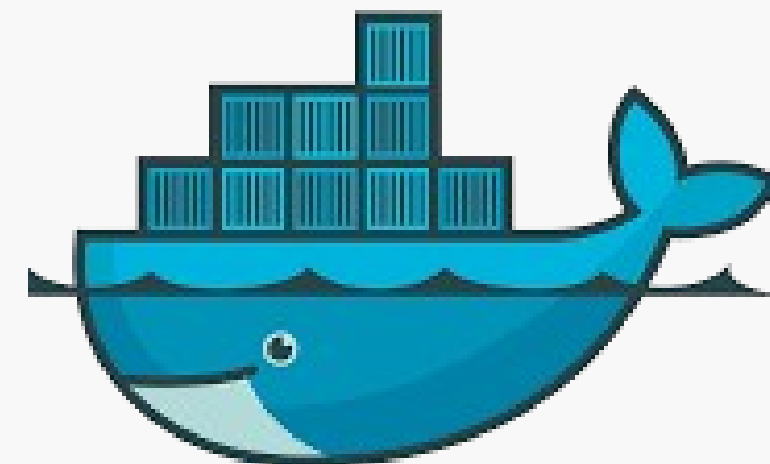

# Solution?

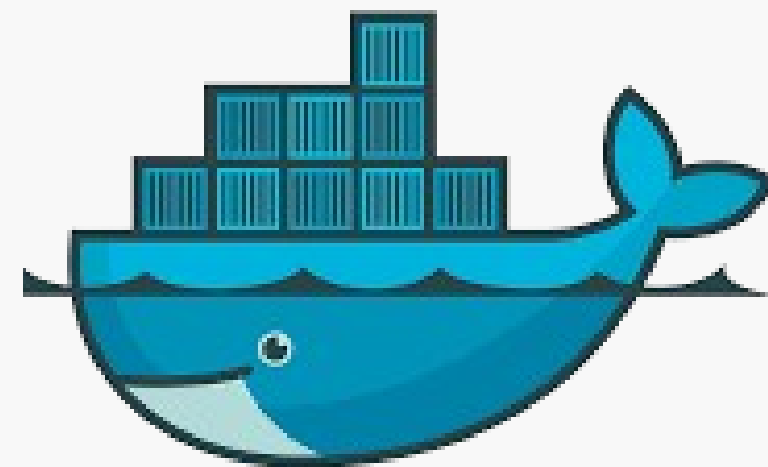

# “Docker”

**Packages everything inside a  
container, ensuring consistency  
across all environments.**

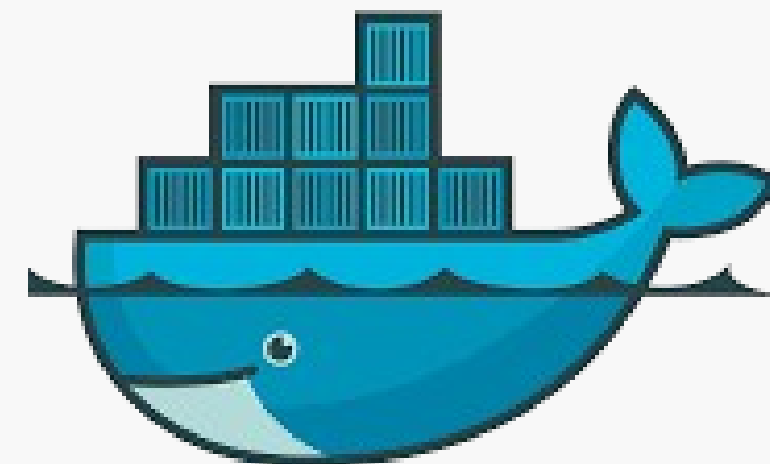

**Runs on any system without  
worrying about dependencies,  
OS versions, or conflicts.**

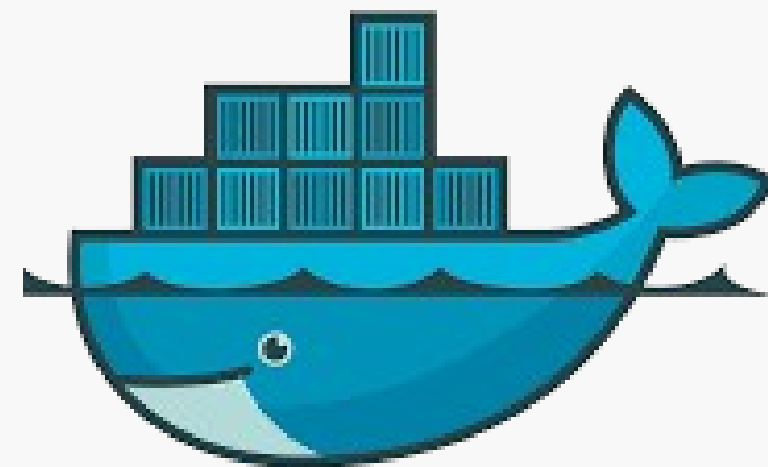

**Faster deployment as containers  
start instantly compared to  
traditional virtual machines.**

**Makes scaling applications easy  
by running multiple containers  
as microservices.**

*Thank you*
